God would be a costly accident: Supernatural beliefs as adaptive

doi:10.1017/S0140525X09991245

Abstract: I take up the challenge of why false beliefs are better than “cautious action policies” (target article, sect. 9) in navigating adaptive problems with asymmetric errors. I then suggest that there are interactions between supernatural beliefs, self-deception, and positive illusions, rendering elements of all such misbeliefs adaptive. Finally, I argue that supernatural beliefs cannot be rejected as adaptive simply because recent experiments are inconclusive. The great costs of religion betray its even greater adaptive benefits – we just have not yet nailed down exactly what they are.

The greatest challenge to McKay & Dennett’s (M&D’s) argument is why false beliefs are necessary to achieve adaptive behavior – why not (as M&D note in sect. 9, para. 2) just have “cautious action policies” instead? I don’t believe this problem was completely resolved in the target article, so I tackle it with reference to the “supernatural punishment hypothesis” (Johnson 2004; Johnson & Bering 2006; Johnson & Krüger 2004), since the same problem haunts that hypothesis as well.

The argument is that the costs of selfishness increased when humans evolved language and Theory of Mind (ToM), because social transgressions became much more likely to be detected and punished. Supernatural punishment offered a cautionary mind-guard to reduce selfishness and avoid real-world costs. But why bring God into it? A Darwinian perspective suggests that atheists could simply develop a “cautious action policy” – becoming more prudent about when to be selfish. A first line of defense comes from M&D’s categories of evolutionary limitations: (1) economics – a fear of supernatural agency may have been biologically cheaper or more efficient; (2) history – a capacity for supernatural beliefs may have been more readily available, given the prior evolution of ToM; (3) adaptive landscape – fear of detection and punishment by supernatural agents may have been a small step up the local fitness peak from fear of detection and punishment by human agents.

A stronger line of defense is that, while a cautious action policy might work in principle, the whole point of error management theory is that it pays to overestimate the probability of detection, not to get it right or to weigh up the costs and benefits “rationally” (Haselton & Buss 2000; Haselton & Nettle 2006; Nettle 2004). Believing (irrationally) that supernatural agents are watching is a good way to ensure systematic overestimation of the actual risk of detection and punishment (by other human beings; Johnson 2009). The power of religion appears to stem precisely from its irrational and non-falsifiable features (Rappaport 1999), and empirical data suggest that religious beliefs are more effective at promoting group survival than similar but non-religious beliefs (Sosis & Bressler 2003). Cautious action policies might work in reducing selfishness, but they may not be as effective as God.

My next concern is that supernatural agency, self-deception, and positive illusions are treated as independent phenomena, with only positive illusions making the cut for an adaptive misbelief. However, there are important interactions between these three phenomena that make elements of all of them adaptive.

First, self-deception is essential to many supernatural beliefs. If supernatural punishment is to affect people’s behavior, they must believe in it – despite lacking any direct evidence whatsoever and despite having to ignore counter-evidence. This is classic self-deception (Trivers 2000). Interestingly, this self-deception can be reinforced by the belief itself – in many religions, it is common for someone’s misfortune to be treated as evidence of wrongdoing, since gods or spirits “evidently” punished the victim (Bering & Johnson 2005).

Second, self-deception is essential to many positive illusions. For example, positive illusions have been suggested to be adaptive in conflict, bluffing superior power or skill to deter opponents (Johnson 2004; Trivers 2000; Wrangham 1999). Self-deception is essential here to avoid “behavioral leakage” that would otherwise give the game away (nervous Nellies are less convincing bluffers than cool-hand Lukes). This may be why, as Daniel Kahneman notes, “all the biases in judgment that have been identified in the last 15 years tend to bias decision-making toward the hawkish side” (quoted in Shea 2004). Positive illusions appear to be advantageous enough that numerous psychological biases converge to promote them despite the evidence.

Third, supernatural beliefs may be an example of positive illusions. As M&D note, people often cite God as giving them “the strength to go on.” If health or fitness advantages derive from such beliefs, then religious beliefs are adaptive according to M&D’s own criteria. Religious beliefs may involve all three types of positive illusions: positive self-evaluations (God chose me/us), illusions of control (God will help me/us in difficult times), and optimism about the future (God has a plan; Heaven awaits). Similar beliefs are common among the world’s numerous religions.

My final concern is M&D’s rejection of supernatural beliefs as adaptive, which hinges on a perceived lack of empirical evidence. This is problematic for three reasons. First, in the literature M&D focus on, researchers tend to use religious primes derived from Western Judeo-Christian traditions (e.g., “divine,” “God,” and “prophet” in Shafir & Norenzayan 2007), whereas the relevant supernatural concepts in our evolutionary history could be anything from dead ancestors, spirits, ghosts, witches, inanimate objects, and so forth. Similarly, modern religious agents are only one possible type of supernatural agency, whereas subjects’ behavior may also be influenced by other sources such as superstition, folklore, karma, Just World beliefs (the belief that victims of tragedy somehow deserved it), or everyday “comeuppance” and “just deserts.” Given this diversity of possible supernatural agents and sources, personal religious
affiliations and devoutness among experimental subjects may be somewhat independent of how supernatural beliefs – in general – influence people’s behavior (M&D predict an interaction of personal religious devoutness and behavior). Current experiments may not, therefore, be able to differentiate the behavior of “believers” and “non-believers” – Joe Bloggs may be an avowed atheist who, on his way to Las Vegas, is nevertheless very concerned about seeing a black cat or wearing his lucky jacket or what his grandmother would have said.

Second, even if we had incontrovertible evidence that supernatural cues (e.g., via experimental primes) promoted higher donations in economic games, this is far from evidence that religious beliefs are biologically adaptive. On the contrary, it could be evidence that religious primes turn people into suckers who give away precious resources. Such behavior, on its own, would not survive natural selection – without additional field experiments measuring fitness consequences, evidence for altruism is hardly evidence of an adaptive trait. Therefore, the (excellent) current laboratory experiments that M&D focus on cannot yet be used as deal-breakers as to whether (mis)belief is adaptive or not.

Third, having rejected supernatural beliefs as adaptive, M&D’s null hypothesis is that religious beliefs are a non-adaptive byproduct of cognitive mechanisms adapted for other purposes – evolutionary accidents, in other words. However, if religious beliefs are accidental byproducts, we might expect natural selection to have eradicated them because (as M&D note) they impose significant fitness costs in terms of time, effort, and resources (Sosis & Alcorta 2003). So why do they persist?

Even if some religious beliefs persist as “sticky” cultural parasites, it does not preclude them from also promoting individual or group fitness at certain times or contexts (in which case they may not be “parasites”). The universality and power of religious beliefs of some form or other – despite their costs – to billions of people around the world, every culture in history, and every hunter-gatherer society, strongly suggests that religion confers adaptive fitness benefits, for individuals and/or groups (at least in some contexts, for some people, and for some periods of human history). Of course, universality need not imply adaptation: other non-adaptive traits such as chins and male nipples are also globally and historically universal. However, they do not impose significant costs. Religion does.

The only theories that solve this paradox are religion-as-adaptive hypotheses that propose how costly (mis)beliefs beget even greater benefits for individuals and/or groups (Johnson 2008; Norenzayan & Shariff 2008; Sosis & Alcorta 2003; Wilson 2002), or are outweighed by the costs of non-belief (Cronk 1994; Johnson 2009; Johnson & Bering 2006). Byproduct theories of religion offer no solution to its greatest puzzle, for God would be a costly accident.

A positive illusion about “positive illusions”?

doi:10.1017/S0140525X09991257

Abstract: Rather than being a genuine adaptation, “positive illusions” are examples of doxastically uncommitted policies implemented at both the individual and societal levels. Even when they are genuine misbeliefs, most positive illusions are not evolved but ephemeral – a phenomenon limited to a particular social and economic moment. They are essentially a consumer response to messages from the pop-psychology industry in the recently terminated era of easy credit.

The article by McKay & Dennett (M&D) presents a thoughtfull classification and analysis of the evolutionary issues involved in misbelief. The notion that certain misbeliefs may arise through the normal functioning of the belief-formation system (as opposed to its breakdown), by virtue of relying on incomplete or inaccurate information, is clearly acceptable (and not new). What is debatable, however, is the authors’ key proposition, that a subclass of such misbeliefs has been systematically adaptive in the evolutionary past. The usefulness of this suggestion depends to a large extent on finding an example that meets the authors’ commendably sound and strict criteria, yet the sole example of adaptive, evolved misbelief that is proposed by M&D, “positive illusions,” is not convincing.

One should first note that the concept of positive illusions, as well as the term itself and psychologists’ (mis?)beliefs about the positive consequences of self-serving distortions of reality, are all of quite recent vintage (e.g., Taylor 1989). M&D helpfully contrast this view of mental health with Jahoda’s (1958) earlier and more measured one. Whether or not one wishes to engage in culture-theorizing about the contrast between the fear of social ridicule and the self-restraint evident in the Eisenhower era (demonstrated, for example, in Asch’s [1956] “social conformity” experiments), on one hand, and the less-disguised greed and self-promotion of the more recent I-want-it-all-now generations, on the other, the fact is that the content of many positive illusions is a quite recent phenomenon and that the results of many of the studies are likely to be ephemeral and support Gergen’s (1973) “social psychology as history” view. It is therefore risky (if not unwarranted) to be talking about the creation and implementation of misbelief as adaptive – let alone adapted – selection-driven behaviors (see the authors’ Note 3).

There are also questions about the empirical evidence marshaled by M&D (all of it dating from after about 1985). A number of studies purporting that “most people . . . see themselves as better than most others on a range of dimensions” (target article, sect. 2.2) appear to be methodologically unsound. M&D should have more closely examined the presence of problems and alternative explanations related to the framing of questions, the differential social desirability of various response alternatives, and the Pygmalion effect before implying that positive illusions were present and favored in the ancestral environment. In addition, quotes from psychologists firmly committed to the environmentalist position – such as the social-learning theory, with its (mis?)beliefs about the teachability and ready amelioration of just about every personal shortcoming – cannot be considered an entirely unbiased source.

Other studies have tended to ignore the participants’ referential framework and may not have dealt with misbeliefs. For example, people who claim that their current partner is better than most are likely to be referring to their past partners’ failings and the undesirable traits and behaviors of people in all those failed marriages that they know and read about. Even with regard to an inflated opinion of one’s children, studies have presumably not polled the opinions of the parents (including potential ones) who terminated pregnancies – or who committed infanticide, physical and/or sexual abuse, and the more common acts of neglect. If even such parents, as is possible and even likely, were to have an inflated idea of the merits of their offspring and potential offspring, this would raise interesting questions about the meaningfulness of using the questionnaire-retrospective research approach to probe matters relevant to evolutionary adaptation.

To the extent that positive illusions can, in fact, be adequately documented (regardless of whether or not they are evolved, adaptive misbeliefs), it is of interest to try to place them in a broader contemporary context. If people’s positive illusions about their personal worth and ability are translated into behavior evident to others, all sorts of negative consequences are likely to ensue, from mild ridicule to severe ostracism. Unless, that is, the unbridled expression of positive illusions has been
